

## FLEXIBLE HEAT EXCHANGER

### FIELD OF THE INVENTION

The present invention relates to a flexible heat  
5 exchanger having a conduit pattern through which a fluid  
passes.

### BACKGROUND OF THE INVENTION

AIAA-77-764 describes a flexible radiator for space  
10 vehicles which comprises a resinous or metallic pipe  
through which a refrigerant passes, a binder film binding  
the pipe, and a metal film.

Japanese Patent No. 3,084,814 describes a rigid  
radiator for space vehicles which comprises a conduit  
15 through which a refrigerant passes.

### SUMMARY OF THE INVENTION

It is an object of the present invention to provide  
a flexible heat exchanger having a conduit pattern  
20 through which a fluid passes.

It is another object of the invention to provide a  
flexible heat exchanger having a simple structure.

The invention resides in a flexible heat exchanger  
comprising a pair of flexible thermoplastic polymer films  
25 which are in part fused together, whereby producing be-  
tween the polymer films a conduit pattern through which a  
fluid passes.

### BRIEF DESCRIPTION OF THE DRAWINGS

30 Fig. 1 illustrates views indicating an example of a  
flexible heat exchanger of the invention and one method  
for manufacturing the flexible heat exchanger.

Fig. 2 illustrates a set of flexible thermoplastic  
intervening films for forming a conduit pattern in combi-  
35 nation which are placed between a pair of flexible ther-  
moplastic cover films.

Fig. 3 illustrates a copper foil in the form of a conduit pattern for forming a conduit which are placed between a pair of flexible thermoplastic cover films.

Fig. 4 illustrates a structure in which a flexible  
5 heat exchange of the invention is attached to a space vehicle.

#### DETAILED DESCRIPTION OF THE INVENTION

Preferred embodiments of the invention are described  
10 below:

(1) The flexible thermoplastic polymer films are flexible thermoplastic polyimide films.

(2) The flexible thermoplastic polymer films are composite films comprising a heat-resistant aromatic  
15 polyimide substrate film and a thermoplastic aromatic polyimide surface film fixed to the substrate film.

(3) The flexible thermoplastic polymer films are flexible thermoplastic polyethylene terephthalate films.

(4) The flexible heat exchanger has a heat conduc-  
20 tive film on a surface thereof.

(5) In the flexible heat exchanger, a flexible film having a heat radiant metal layer on one side is fixed to the heat conductive film.

(6) The flexible heat exchanger has a heat resis-  
25 tant porous film on a surface having no heat conductive film thereon.

(7) The flexible heat exchanger has a thickness of 25  $\mu\text{m}$  to 20 mm, preferably 25 to 200  $\mu\text{m}$ .

(8) The flexible heat exchangers are placed one on  
30 another to produce a multi-layered flexible heat exchanger.

(9) A space vehicle having the flexible heat exchanger (used as a heat radiator) on a surface thereof. See Fig. 4 in which the flexible heat exchanger 1 of the  
35 invention is attached to a space vehicle 10.

(10) An electronic apparatus such as a personal

computer having the flexible heat exchanger on a surface thereof.

(11) An electronic part such as a flexible circuit board having the flexible heat exchanger on a surface thereof.

(12) A solar heat collector having the flexible heat exchanger on a surface thereof.

The present invention is further described below by referring to the attached drawings.

The flexible heat exchanger of the invention comprises a pair of flexible thermoplastic polymer films which are in part fused together, whereby producing between the polymer films a conduit pattern through which a fluid passes.

The pair of flexible thermoplastic polymer films produce in combination a structure in which a conduit pattern is formed.

The flexible thermoplastic polymer films, namely, cover films, can be polyimide films, polyester films (e.g., polyethylene terephthalate films), polyamide films, ethylene polymer films, or elastomer films. The polyimide films and polyethylene terephthalate films are preferred.

The flexible thermoplastic polymer film preferably has a thickness of 10 to 125  $\mu\text{m}$  and a glass transition temperature (or a melting point or a softening point) of 190 to 300°C. The flexible thermoplastic polymer film may contain an inorganic filler or other additives for increasing heat conductivity of the polymer film.

The flexible thermoplastic polyimide film can be a single layer film or a multilayer film comprising a high heat resistant polyimide substrate film and a thermoplastic polyimide surface film. The multilayer polyimide film preferably comprises a heat resistant substrate film of 5 to 120  $\mu\text{m}$  thick, more preferably 5 to 75  $\mu\text{m}$  thick and a thermoplastic surface film of 2 to 10  $\mu\text{m}$  thick.

The multilayer polyimide film can be prepared by the steps of combining a solution film of a polyimide precursor solution (i.e., polyamic acid solution) for the high heat resistant polyimide substrate and a solution film of a polyimide precursor solution (i.e., polyamic acid solution) for the thermoplastic polyimide surface film, and heating the combined solution films to convert them the multilayer polyimide film. Detailed process is as follows. A dope solution I (polyamic acid solution for the high heat resistant polyimide substrate) and a dope solution II (polyamic acid solution for the thermoplastic polyimide surface film) were placed in a multi-manifold type molding die for three film extrusion. A combination of the dope solution II, the dope solution I, and the dope solution II was simultaneously extruded from the die and casted on a stainless steel belt support. The casted solution films were dried by continuously applying an air heated to 100-200°C, to give a solid film. The solid film was separated from the support and placed in a heating furnace to gradually heating the solid film from 300°C to 400°C. Thus, the solvent was removed and the film was imidized to give a polyimide film.

The thermoplastic polyimide film can be produced from aromatic tetracarboxylic acid compounds comprising 2,3,3',4'-biphenyltetracarboxylic dianhydride (a-BPDA) and 4,4'-oxydiphthalic dianhydride and diamine compounds such as 1,3-bis(4-aminophenoxybenzene) (TPE-R) or 1,3-bis(3-aminophenoxybenzene) by polymerization and imidization.

The high heat resistant polyimide substrate film preferably has no glass transition temperature or a glass transition temperature ( $T_g$ ) of approx. 340°C or higher and can be produced from aromatic tetracarboxylic acid compounds such as 3,3',4,4'-biphenyltetracarboxylic dianhydride (s-BPDA) or pyromellitic dianhydride and diamine compounds such as p-phenylenediamine (PPD) or a combina-

tion of PPD and 4,4'-diaminophenyl ether, by polymerization and imidization.

The above-mentioned multilayer polyimide film preferably has a linear expansion coefficient (MD, TD and  
5 their average, at 50-200°C) of  $10 \times 10^{-6}$  to  $35 \times 10^{-6}$  cm/cm/°C.

The flexible heat exchanger of the invention can be manufactured in principle by a method comprising the steps of placing one flexible thermoplastic polymer film on another flexible thermoplastic polymer film and fusing  
10 both polymer films in part to combine both polymer films together in part to form the conduit pattern between the polymer films.

The flexible heat exchanger of the invention is preferably manufactured by a method comprising the steps  
15 of placing one flexible thermoplastic polymer film on another flexible thermoplastic polymer film via an intervening flexible thermoplastic polymer film from which a conduit pattern is already cut out, and fusing both polymer films on the intervening flexible thermoplastic polymer film to combine both polymer films together in part  
20 to form the conduit pattern between the polymer films.

The above-mentioned method is explained referring to Fig. 1 of the attached drawings.

In Fig. 1, an intervening flexible thermoplastic polymer film 3 having a reverse pattern of a predetermined conduit pattern is placed between a pair of flexible thermoplastic polymer films (i.e. cover films) 2, 2'.  
25 On one cover film 2 is placed a heat conductive sheet 5. The multilayer structure of the heat conductive sheet 5, cover film 2, intervening film 3, and cover film 2' is heated under pressure. Thus, a composite structure is produced. In the structure, the cover film 2 and cover film 2' are firmly fused together via the intervening film 3 which produces a conduit pattern between the cover  
30 films. To the cover film 2 is fixed the heat conductive sheet. Then, a flexible film 6 having a heat radiant

metal layer on one side is fixed to the heat conductive sheet 5. Subsequently, a fluid (gas or liquid such as ammonium gas, water, fluorinated liquid (e.g., Florinate available from 3M Corporation) is introduced under pressure into the conduit pattern so as to produce the desired conduit, as is illustrated in Fig. 1. Thereafter, a set of an inlet tube 41 and an outlet tube 42 are fixed to the inlet and outlet of the conduit. Thus, the desired flexible heat exchanger 1 of the invention is manufactured.

Fig. 2 illustrates an example of the thermoplastic intervening film having a reverse pattern of a conduit pattern.

In the above-mentioned manufacturing method, it is preferred that the heat conductive sheet (or film) has a heat conductivity of 350 W/mk or higher and a thickness of 10  $\mu$ m to 2 mm. An example of the heat conductive sheet is graphite sheet (e.g., PGS Graphite Sheet, available from Matsushita Electronic Parts Co., Ltd.).

An example of the flexible films having a heat radiant metal layer on one side is a polymer film having a vacuum deposited metal layer. The metal layer preferably comprises gold, aluminum, or silver. There can be mentioned a silver-deposited FEP film, a silver-deposited PTFE film, an aluminum-deposited polyimide film, and a silver-deposited polyether-imide film. These metal-deposited films can have an electroconductive or oxide film such as ITO film,  $\text{SiO}_x$  film, alumina film, or germanium film on the metal layer.

The flexible heat exchanger manufactured above may have a heat resistant porous film on a surface having no heat conductive film thereon. The heat resistant porous film may be a porous resin film such as a porous polyimide film having a thickness of 5  $\mu$ m to 10 mm. To the heat conductive porous film may be fixed a heat resistant polyimide film.

The heat conductive film, flexible films having a heat radiant metal layer, heat resistant porous film, and heat resistant polyimide film can be fixed to the flexible heat exchanger by an a heat resistant adhesive such as polyimide adhesive. However, an acrylic tacky adhesive or a silicon adhesive may be used, depending on the desired used of the heat exchanger.

Otherwise, the flexible heat exchanger of the invention can be manufactured by any of the following methods.

(1) A method comprising the steps of placing one flexible thermoplastic polymer film on another flexible thermoplastic polymer film via a copper foil having a conduit pattern, fusing both polymer films to combine both polymer films together in part, and etching out the copper foil to form the conduit pattern between the polymer films. This method is described in more detail in the below-mentioned Examples 2 and 3. In Fig. 3, an example of the copper foil having a conduit pattern is illustrated.

(2) A method comprising the steps of placing one flexible thermoplastic polymer film on another flexible thermoplastic polymer film, heating both polymer films in a conduit pattern by applying heat to both polymer films via a heat insulating material in the conduit pattern, and fusing both polymer films to combine both polymer films together in part to form the conduit pattern between the polymer films. This method is described in more detail in the below-mentioned Example 1.

(3) A method of manufacturing the flexible heat exchanger of claim 1 which comprises the steps of placing one flexible thermoplastic polymer film on another flexible thermoplastic polymer film, heating both polymer films in a conduit pattern by applying heat to both polymer films by means of a thermal head in a reverse pattern of the conduit pattern, and fusing both polymer films on the intervening flexible thermoplastic polymer film to

combine both polymer films together in an area other than the conduit pattern to form the conduit pattern between the polymer films.

- 5 (4) A method comprising the steps of placing one flexible thermoplastic polymer film on another flexible thermoplastic polymer film via a heat-insulating film in a conduit pattern, fusing both polymer films to combine both polymer films together in an area other than the conduit pattern part, and removing the heat-insulating  
10 film to form the conduit pattern between the polymer films.

The present invention is further described by the following examples.

- 15 [Preparation of flexible thermoplastic polyimide film I)

A polyamic acid solution (for heat resistant substrate film) prepared from a combination of s-BPDA and PPD and a polyamic acid solution (for thermoplastic surface film) prepared from a combination of a-BPDA and TPE-  
20 R were simultaneously extruded from a multi-slit die to prepare a three-layered polyimide film comprising two surface films and one substrate film. The physical characteristics of the three-layered polyimide film are set forth below:

- 25 total thickness: 25  $\mu\text{m}$   
Tg of the surface layer: 255°C  
thermal linear expansion (50-200°C):  $19 \times 10^{-6}$  cm/cm/°C

[Preparation of flexible thermoplastic polyimide film II)

- 30 The procedure for preparing the flexible thermoplastic film I was repeated except for employing a polyamic acid solution (for thermoplastic surface film) prepared from a combination of a-BPDA(20 mol%)+ s-BPDA(80 mol%) and TPE-R to prepare a three-layered polyimide film comprising two surface films and one substrate film. The  
35 physical characteristics of the three-layered polyimide

film are set forth below:

total thickness: 25  $\mu\text{m}$

Tg of the surface layer: 261°C

thermal linear expansion (50-200°C):  $19 \times 10^{-6}$  cm/cm/°C

5

[Example 1]

The following elements were placed in order:

Stainless steel sheet (SUS, 200 mm x 200 mm x 1.5 mm) - releasing polyimide film (Upilex S available from  
10 Ube Industries, Ltd., 200 mm x 200 mm x 25  $\mu\text{m}$ ) - silicone  
rubber sheet (150 mm x 150 mm x 1 mm) - polyimide films  
(Upilex S, 200 mm x 200 mm x 25  $\mu\text{m}$ ) - two flexible ther-  
moplastic polyimide films I (100 mm x 100 mm x 25  $\mu\text{m}$ ) - a  
15 set of heat insulating sheets forming a reverse pattern  
of a conduit pattern (see Fig. 2, made of an aromatic  
polyamide non-woven cloth, Technola Felt, available from  
Teijin Corporation, 210 g/m<sup>2</sup>) - releasing polyimide film  
(Upilex S, 200 mm x 200 mm x 25  $\mu\text{m}$ ) - stainless steel  
sheet (SUS, 200 mm x 200 mm x 1.5 mm).

20 Thus formed laminate was placed in a single-acting  
compression press (available from Sindo Metal Industries,  
Co., Ltd.) equipped with a upper heater heated to 320°C  
and a lower heater heated to 90°C. The laminate was then  
pressed at a pressure of 5 MPa for one minute to give a  
25 heat exchanger of the invention (thickness: 50  $\mu\text{m}$ ) having  
a conduit pattern. It was confirmed that water passed  
through the conduit of the heat exchanger, and the heat  
exchanger can be rolled to give a roll having a diameter  
of 10 mm.

30

[Example 2]

The following elements were placed in order:

Stainless steel sheet (SUS, 200 mm x 200 mm x 1.5 mm) - releasing polyimide film (Upilex S, 200 mm x 200 mm  
35 x 25  $\mu\text{m}$ ) - silicone rubber sheet (150 mm x 150 mm x 1 mm)  
- polyimide film (Upilex S, 200 mm x 200 mm x 25  $\mu\text{m}$ ) -

flexible thermoplastic polyimide film I (100 mm x 100 mm x 25  $\mu$ m) - copper foil having a conduit pattern (see Fig. 3, USLPR2-9, available from Japan Electrolysis Co., Ltd, thickness: 9  $\mu$ m) - flexible thermoplastic polyimide film I (100 mm x 100 mm x 25  $\mu$ m) - releasing polyimide film (Upilex S, 200 mm x 200 mm x 25  $\mu$ m) - stainless steel sheet (SUS, 200 mm x 200 mm x 1.5 mm).

Thus formed laminate was placed in a vacuum press (KVHC-PRESS, available from Kitagawa Precision Machine, Co., Ltd.). The laminate was then pressed at a pressure of 5 MPa at room temperature, heated to 340°C for 40 minutes, and placed for 3 minutes. Subsequently, the laminate was cooled at room temperature for 50 minutes.

Into the copper foil layer was introduced a ferrous chloride-etching solution to dissolve the copper foil. The space formed by the dissolution of copper foil was washed with 3% aqueous hydrochloric acid and water, to completely removing the etched copper foil, to give a heat exchanger of the invention (thickness: 50  $\mu$ m) having a conduit pattern. It was confirmed that water passed through the conduit of the heat exchanger, and the heat exchanger can be rolled to give a roll having a diameter of 10 mm.

[Example 3]

The procedures of Example 2 were repeated except that the flexible thermoplastic polyimide films I were replaced with the flexible thermoplastic polyimide films II to give a heat exchanger of the invention (thickness: 50  $\mu$ m) having a conduit pattern. It was confirmed that water passed through the conduit of the heat exchanger, and the heat exchanger can be rolled to give a roll having a diameter of 10 mm.
